

INVESTOR BRIEFING

A live Layer 1 with **deterministic finality** and smart accounts built in.

Solen is a from-scratch, Rust & WebAssembly proof-of-stake blockchain — mainnet-live, BFT-finalized, and shipping a full product stack: native account abstraction, liquid staking, a token launchpad, and L2 tooling.

A complete, production L1 — not a whitepaper.

Most new chains pitch a thesis. Solen ships a running network. The protocol, virtual machine, consensus, wallet stack, and core DeFi primitives are built, deployed, and finalizing real blocks on mainnet today — engineered end-to-end in Rust for safety and performance.

CRITICAL AUDIT FINDINGS RESOLVED

Why it stands out

- **Account abstraction is native**, not bolted on — every account is a smart account supporting multisig, passkeys, social recovery and gas sponsorship.
- **Deterministic BFT finality** — blocks are irreversible the moment they reach >2/3 stake, with no probabilistic confirmations.
- **Full ownership of the stack** — consensus, VM, networking, and SDKs are first-party Rust, not a fork.
- **Quantum-ready by design** — opt-in NIST post-quantum (ML-DSA-65) and hybrid signatures, made practical by the smart-account model.

Already shipped

- Mainnet running an 11-validator BFT network with public RPC infrastructure.
- **stSOLEN** liquid staking and an on-chain **token launchpad**, both live on mainnet.
- Explorer, faucet, dapp connector, and Rust + TypeScript wallet SDKs.
- An independent security review with all critical findings remediated.

Users want wallets that feel like apps.

The biggest barrier to mainstream on-chain adoption isn't throughput — it's the wallet. Seed phrases, gas tokens, and irreversible mistakes keep ordinary users out. Existing L1s are retrofitting account abstraction onto designs that never assumed it. Solen was designed around it from the first block.

Onboarding without seed phrases

Passkey / WebAuthn authentication and guardian-based social recovery let users sign with a fingerprint and recover without a 12-word phrase — the UX bar set by modern apps.

Gasless & sponsored transactions

Native paymasters let apps pay fees for their users, or accept fees in other assets. New users never need to acquire a gas token first.

Safety by construction

Multisig thresholds, session keys with budgets, and spending controls are protocol primitives — not fragile contract add-ons — reducing the catastrophic-loss surface.

Finality institutions can trust

Single-slot BFT finality means a confirmed transaction is final. No reorg risk, no "wait N blocks" — a prerequisite for serious payments and settlement.

Positioning. Solen competes not on raw TPS marketing but on the things that actually convert users and institutions: a wallet experience that hides crypto's sharp edges, finality you can settle against, and a fully-owned codebase the team can evolve without waiting on an upstream fork.

A modern L1, engineered in Rust.

Sixteen purpose-built crates spanning cryptography to consensus to the VM — a coherent, memory-safe system rather than a patchwork of forks.

CONSENSUS

BFT proof-of-stake. Stake-weighted proposer rotation; blocks finalize at >2/3 committed stake with domain-separated, chain-bound attestations. Attestation-aware fork choice (v2) guarantees liveness even under validator churn.

EXECUTION

WebAssembly VM (Wasmtime). Gas is metered as execution fuel; deterministic floating-point and bounded memory ensure every validator computes an identical state root. Reentrancy is prevented by design.

ACCOUNTS

Smart accounts by default. Pluggable authentication — Ed25519, threshold multisig, passkey/WebAuthn, and guardian recovery — plus paymasters, session keys, and intents.

STATE

RocksDB + Merkle state root. Atomic block commits and a tiered recovery system (in-memory journal → native checkpoints → local & remote snapshots) for fast, safe restarts.

NETWORK

libp2p P2P. Noise-encrypted, peer-authenticated gossip with connection limits, rate-limiting, and peer reputation. Snapshot sync for rapidly bootstrapping new nodes.

INTERFACES

JSON-RPC, indexer/explorer, CLI, and SDKs. Rust and TypeScript wallet SDKs; a browser dapp connector; faucet and public RPC behind a load-balanced edge.

Cryptography

Ed25519 (strict verification, non-malleable) for signatures · BLAKE3 for hashing & state Merkleization · SHA-256 + P-256 for WebAuthn passkeys · AES-256-GCM with Argon2id for encrypted key storage.

Reliability

24×7 fleet monitoring with automated alerting; deterministic crash-consistent recovery; coordinated, gated upgrade process for consensus-affecting changes — demonstrated through live incident response.

A full product surface, on-chain.

Beyond the base protocol, Solen ships the system contracts and tooling an ecosystem actually needs — many already live on mainnet.

Smart accounts & recovery

Ed25519, threshold multisig, passkey/WebAuthn, and guardian social recovery — all first-class account types.

Quantum-ready accounts

Opt-in NIST post-quantum signatures (ML-DSA-65, FIPS 204) and a hybrid mode (classical + PQ). One CLI command upgrades an account — same address, no fund migration.

Paymasters & sponsorship

Apps sponsor user gas or accept fees in other assets, enabling truly gasless onboarding.

Liquid staking — stSOLEN

LIVE

Stake SOLEN, receive a liquid receipt token that accrues rewards while staying usable in DeFi.

Token launchpad

LIVE

On-chain launchpad for new projects to issue and distribute tokens on Solen.

On-chain governance

Stake-weighted proposals with flash-vote protection govern protocol parameters and the treasury.

Treasury & vesting

Protocol treasury funded by fee revenue, plus native vesting vaults for teams and contributors.

Intents

Declarative "what, not how" transactions fulfilled by solvers — the foundation for advanced wallet UX.

Rollup kit & bridge

L2 tooling with committee-attested proof verification and a bridge framework for scaling and interoperability.

Developer SDKs

Rust & TypeScript wallet SDKs, a WASM contract SDK, and a browser dapp connector.

Explorer, indexer & faucet

Block explorer and indexer API, public RPC, and a testnet faucet for builders.

A security-first engineering culture.

Solen commissioned a deep independent security review of the entire codebase — consensus, VM, economics, networking, and wallets. Rather than bury it, the team has driven remediation in the open, shipping fixes to mainnet through a disciplined, gated upgrade process.

MEMORY-SAFE RUST

24×7

FLEET MONITORING

What was hardened

- **Supply integrity** — fee settlement is provably conservative; no value can be minted.
- **Consensus authenticity** — block sync and peer messages are validator-authenticated, closing forgery and eclipse vectors.
- **Deterministic execution** — VM memory and SIMD behavior pinned so honest nodes never diverge.
- **DoS resistance** — connection limits, rate-limiting, and bounded RPC work across the network surface.
- **Quantum readiness** — opt-in ML-DSA-65 / hybrid account signatures, cross-implementation verified, ahead of the post-quantum transition.

How we ship safely

- Consensus-affecting fixes are deployed **dormant behind activation gates**, then enabled fleet-wide in a single coordinated step.
- Upgrades roll one validator at a time with full re-sync verification — proven through live incident recovery with zero state loss.
- Tiered crash recovery and a verifiable Merkle state root mean any node can prove it is on the canonical chain.
- Remaining medium/low findings are tracked and being addressed on a published path.

The takeaway for investors: a team that seeks out hard security review, fixes the hard things first, and operates the network with institutional discipline — exactly the maturity that de-risks a young L1.

Mainnet is live and operated like infrastructure.

Network

- Mainnet and testnet both operational.
- 11-validator BFT consensus set, equal-stake.
- 4 dedicated public-RPC nodes behind a load-balanced, TLS edge (`rpc.solchain.io`).
- Snapshot infrastructure for fast node bootstrapping.
- Continuous monitoring with automated incident alerting.

Live applications

- **stSOLEN** — liquid staking protocol (mainnet).
- **Launchpad** — token issuance & distribution (mainnet).
- **Explorer & indexer** — chain data and APIs.
- **Solen dapp connector** — browser wallet bridge used by ecosystem dapps.
- **Faucet & SDKs** — builder onboarding.

SOLEN — a fixed-supply, deflationary asset.

2,000,000,000

FIXED TOTAL SUPPLY

50%

OF FEES BURNED (DEFLATIONARY)

Non-inflationary

REWARDS PAID FROM POOL, NOT MINTED

How value accrues

- **Fee burn.** A configurable share of every transaction fee (currently 50%) is permanently removed from supply — usage is deflationary.
- **Conservative emission.** Staking rewards are paid from a funded staking pool rather than minted, avoiding open-ended inflation.
- **Staking demand.** Securing the network and earning rewards (incl. via liquid stSOLEN) creates persistent demand to hold and stake.
- **Treasury.** The remaining fee share funds an on-chain, governance-controlled treasury for ecosystem growth.

Allocation

Distribution across Solen's genesis categories. Team and investor allocations vest on-chain via native vesting vaults.

Ecosystem & community	28%
Staking & validator rewards	22%
Treasury / DAO	18%
Team & core contributors · vested	15%

VISION

The default chain for consumer-grade on-chain apps

A self-sustaining, community-governed network where seedless, gasless, recoverable accounts make on-chain interaction indistinguishable from using a normal app.

Why now.

De-risked by execution

A live, finalizing mainnet and a working product stack — the hardest, most uncertain part is already done.

Differentiated by design

Native account abstraction + deterministic finality target the real adoption blockers, not vanity benchmarks.

Operational maturity

Independent security review, gated upgrades, and proven incident response — institutional-grade discipline.

Sound economics

Fixed supply, deflationary fee burn, and non-inflationary rewards align long-term holders and the network.

The round

Solen is raising to accelerate decentralization, ecosystem growth, and the L2/scaling roadmap.

Target raise: **\$500,000**

Instrument: **SAFT** (Simple Agreement for Future Tokens)

Use of funds: engineering & security audits · validator & RPC infrastructure · exchange listings & BD · ecosystem grants · legal & compliance
